Tidy format (murders data)

We say that a data table is in **tidy** format if each row represents one observation and columns represent the different variables available for each of these observations. For example, the following data is in tidy format:

```
data(murders)
head(murders)
```

```
##
          state abb region population total
## 1
        Alabama
                  AT.
                      South
                               4779736
                                          135
                 ΑK
                       West
                                 710231
                                           19
##
         Alaska
                               6392017
## 3
        Arizona
                  A 7.
                     West
                                          232
                  AR.
                               2915918
                                           93
##
       Arkansas
                      South
   5 California
                  CA
                       West
                              37253956
                                         1257
##
   6
       Colorado
                  CO
                       West
                                5029196
                                           65
```

Not tidy format (fertility)

The following dataset is organized, but not tidy. Why?

```
path <- system.file("extdata", package = "dslabs")</pre>
filename <- file.path(path, "fertility-two-countries-example.csv")
wide data <- read csv(filename)</pre>
## Rows: 2 Columns: 57
## -- Column specification -----
## Delimiter: "."
## chr (1): country
## dbl (56): 1960, 1961, 1962, 1963, 1964, 1965, 1966, 1967, 1968, 1969, 1970,
##
## i Use `spec()` to retrieve the full column specification for this data.
## i Specify the column types or set `show_col_types = FALSE` to quiet this mes
select(wide_data, country, `1960`:`1962`) %>% as.data.frame()
         country 1960 1961 1962
##
        Germany 2.41 2.44 2.47
## 1
## 2 South Korea 6.16 5.99 5.79
```

Tidy format (fertility)

Here is how we would organize these data to be tidy:

```
data("gapminder")
tidy_data <- gapminder %>%
  filter(country %in% c("South Korea", "Germany") &
    !is.na(fertility)) %>%
  select(country, year, fertility)
head(tidy_data, 6)
```

```
## country year fertility
## 1 Germany 1960 2.41
## 2 South Korea 1960 6.16
## 3 Germany 1961 2.44
## 4 South Korea 1961 5.99
## 5 Germany 1962 2.47
## 6 South Korea 1962 5.79
```

Tidy format

The same information is provided, but there are important differences in the format. For the **tidyverse** packages to be optimally used, data need to be reshaped into 'tidy' format. The advantage of working in tidy format allows the data analyst to focus on more important aspects of the analysis rather than the format of the data.

Tidy data wrangling

The **dplyr** package, which is part of the **tidyverse**, presents a basic grammar for wrangling tidy data:

- mutate(): add or modify existing columns
- select(): take a subset of the columns (variables)
- filter(): take a subset of the rows (observations)
- arrange(): sort the rows
- summarize(): aggregate data across rows

Note an important point: most dplyr functions (and most functions in the tidyverse) input a tibble and then output a modified tibble!

Mutate

The function **mutate** takes the data frame, the instructions for the new columns in next arguments, and returns a modified data frame. For example:

head(murders)

```
##
          state abb region population total
                  AT.
                                4779736
## 1
        Alabama
                      South
                                           135
                                 710231
## 2
         Alaska
                  ΔK
                       West
                                            19
                                6392017
                                           232
## 3
        Arizona
                  A7.
                       West
## 4
       Arkansas
                  AR.
                      South
                                2915918
                                           93
## 5 California
                  CA
                     West
                               37253956
                                          1257
##
   6
       Colorado
                  CO
                       West.
                                5029196
                                           65
```

Mutate

To add murder rates, we mutate as follows:

```
murdersRate <- mutate(murders,
   rate = total / population * 100000
)
head(murdersRate)</pre>
```

```
##
         state abb region population total
                                           rate
              AL South
                           4779736
                                    135 2.824424
## 1
       Alabama
      Alaska AK
                            710231 19 2.675186
## 2
                 West
## 3
      Arizona AZ West
                           6392017 232 3.629527
      Arkansas AR South
                           2915918
                                     93 3.189390
## 4
## 5 California
               CA West
                          37253956
                                   1257 3.374138
      Colorado
                           5029196
## 6
               CO West
                                     65 1.292453
```

Filter

Now suppose that we want to filter the data table to only show the entries for which the murder rate is lower than 0.71. We do this as follows:

```
filter(murdersRate, rate <= 0.71)</pre>
##
            state abb
                             region population total
                                                          rate
## 1
           Hawaii
                   ΗT
                               West.
                                       1360301
                                                   7 0.5145920
## 2
             Towa
                   TA North Central
                                       3046355
                                                  21 0.6893484
  3 New Hampshire NH
                          Northeast
                                       1316470
                                                   5 0.3798036
## 4
     North Dakota ND North Central
                                        672591
                                                   4 0.5947151
## 5
          Vermont VT
                          Northeast
                                        625741
                                                   2 0.3196211
```

Select

If we want to view just a few of our columns, we can use the following:

```
murdersRate <- mutate(murders,
    rate = total / population * 100000
)
murdersRateSelect <- select(murdersRate, state, rate)
filter(murdersRateSelect, rate <= 0.71)</pre>
```

```
## state rate
## 1 Hawaii 0.5145920
## 2 Iowa 0.6893484
## 3 New Hampshire 0.3798036
## 4 North Dakota 0.5947151
## 5 Vermont 0.3196211
```

Nesting functions

Instead of defining new objects along the way, we could do everything in one complex nested function:

```
filter(
    select(
        mutate(murders, rate = total / population * 100000),
        state, rate
),
    rate <= 0.71
)</pre>
## state rate
```

```
## 1 Hawaii 0.5145920

## 2 Iowa 0.6893484

## 3 New Hampshire 0.3798036

## 4 North Dakota 0.5947151

## 5 Vermont 0.3196211
```

This is fairly concise but a little confusing. Is there a better way?

Pipes

In the previous example, we performed the following wrangling operations:

original data
$$\,\,
ightarrow\,$$
 mutate $\,\,
ightarrow\,$ select $\,\,
ightarrow\,$ filter

As with Unix, we can perform a series of operations in R by sending the results of one function to another using the **pipe operator**: %>%. As of R version 4.1.0, you can also use |>.

The pipe is a combination of characters that when used properly does two things: *It shortens and simplifies the code* and it makes the code intuitive to read.

Pipes

All the pipe does is provide **forward application** of an object to the first argument of a function. The pipe sends left side of the input to the function to the right of the pipe. For example, if we wanted to calculate

$$\log_2(\sqrt(16))$$

We could use:

```
## [1] 2
```

Since the pipe sends values to the first argument, we can define other arguments as follows:

[1] 2

Pipes (murders)

Completing the prior tibble operation using pipes:

```
murders %>%
  mutate(rate = total / population * 100000) %>%
  select(state, rate) %>%
  filter(rate <= 0.71)</pre>
```

```
## state rate
## 1 Hawaii 0.5145920
## 2 Iowa 0.6893484
## 3 New Hampshire 0.3798036
## 4 North Dakota 0.5947151
## 5 Vermont 0.3196211
```

Note that as you can see, the pipe operators (%>% or |>) are not specific to the tidyverse, in fact they come from the **magrittr** package (which is loaded by the tidyverse and dplyr libraries)

Arrange

We know about the **order** and **sort** functions, but for ordering entire tables, the **arrange** function is much more useful. For example, here we order the states murder rate:

```
murdersRate %>%
  arrange(rate) %>%
  head()
```

```
##
             state abb
                              region population total
                                                           rate
## 1
           Vermont.
                    VT
                           Northeast
                                         625741
                                                    2 0.3196211
                    NH
                           Northeast
                                        1316470
                                                    5 0.3798036
    New Hampshire
## 3
            Hawaii HI
                                        1360301
                                                    7 0.5145920
                                West
## 4
     North Dakota ND North Central
                                         672591
                                                    4 0.5947151
## 5
             Iowa IA North Central
                                        3046355
                                                   21 0.6893484
                                        1567582
                                                   12 0.7655102
## 6
             Tdaho
                    TD
                                West.
```

Arrange (descending order)

Note that the default behavior is to order in ascending order. The function **desc** transforms a vector so that it is in descending order. To sort the table in descending order, we can type:

```
murdersRate %>%
  arrange(desc(rate)) %>%
  head()
```

```
##
                     state abb
                                      region population total
                                                                     rate

```

Nested sorting

If we are ordering by a column with ties, we can use a second (or third) column to break the tie. for example:

```
murdersRate %>%
  arrange(region, rate) %>%
  head()
```

```
##
                       region population total
           state abb
                                                  rate
## 1
         Vermont VT Northeast
                                 625741
                                           2 0.3196211
                                 1316470
                                            5 0.3798036
  2 New Hampshire NH Northeast
## 3
           Maine ME Northeast 1328361 11 0.8280881
##
     Rhode Island RI Northeast 1052567
                                          16 1.5200933
## 5 Massachusetts MA Northeast 6547629
                                          118 1.8021791

         New York NY Northeast
                                19378102
                                          517 2.6679599
```

Summarize

The **summarize** function computes summary statistics in an intuitive way. The 'heights' dataset includes heights and sex reported by students in an in-class survey.

```
data(heights)
heights %>%
  filter(sex == "Female") %>%
  summarize(
   avg = mean(height),
   std_dev = sd(height)
)
```

```
## avg std_dev
## 1 64.93942 3.760656
```

Group then summarize with 'group_by'

A common operation in data exploration is to first split data into groups and then compute summaries for each group. For example, we may want to compute the average and standard deviation for men's and women's heights separately. We can do the following

```
heights %>%
  group_by(sex) %>%
  summarize(
   average = mean(height),
   standard_deviation = sd(height)
)

## # A tibble: 2 x 3
## sex average standard_deviation
```

More on the tidyverse

In as you learn more about the tidyverse you will learn a few more tidyverse operations, including the **inner_join**, **left_join**, **pull**, **dot**, and **do** functions, and the **tidyr** package.
